ABSTRACT: **Introduction**: Breast cancer remains one of the most prevalent and aggressive forms of cancer among women globally. Early detection plays a crucial role in improving survival rates and treatment outcomes. Magnetic Resonance Imaging (MRI) has emerged as a highly sensitive diagnostic tool for identifying breast tumors, especially at early stages where lesions are small and have poorly defined margins. However, accurate segmentation of such tumors from MRI scans is challenging due to their low contrast, heterogeneous intensity distribution, and ambiguous boundaries.

Objectives: This study aims to develop an advanced deep learning architecture for precise and automated segmentation of early-stage breast tumors in MRI images. The proposed method focuses on enhancing tumor boundary detection by integrating global attention mechanisms and shape-aware feature learning, addressing the limitations of conventional models that struggle with small lesion delineation.

Methods: A novel deep learning architecture, named Shape-Enhanced Transformer Encoder U-Net (SETE-UNet), was introduced. This model integrates three key components:

- A U-Net backbone enhanced with residual convolution blocks to prevent gradient vanishing and improve feature extraction.
- A Transformer encoder incorporated into the bottleneck layer to capture long-range dependencies and enhance global context understanding.
- A shape-enhanced branch equipped with Gated Convolutional Layers (GCLs) to selectively refine boundary-related features and improve segmentation accuracy for small and irregularly shaped tumors.

Additionally, a new dataset comprising 260 early-stage breast tumor MRI cases (243 female and 17 male patients) was curated and annotated by expert radiologists. The performance of the proposed architecture was evaluated using standard metrics including MIoU, Dice coefficient, Sensitivity, Specificity, Precision, Accuracy, AUC, and Hausdorff Distance.

Results: Experimental results demonstrated that the SETE-UNet out performed state-of-the-art segmentation models across all evaluation metrics. The model achieved a Dice score of 91.7%, MIoU of 85.8%, Sensitivity of 80.9%, Specificity of 95.8%, and the lowest Hausdorff Distance of 2.20, indicating superior accuracy and boundary alignment compared to existing methods. Visual analysis confirmed improved delineation of small and ambiguous tumors, reducing both false positives and missed detections.

Conclusions: The proposed SETE-UNet effectively addresses the challenges of early-stage breast tumor segmentation by leveraging global attention mechanisms and boundary-aware feature learning. The integration of Transformer-based modeling and

shape-enhanced processing significantly enhances segmentation accuracy and robustness. This approach holds great potential for clinical applications, offering reliable support for early diagnosis and reducing the burden on radiologists.

INTRODUCTION

According to the global cancer statistics published by the "World Health Organization's International Agency for Research on Cancer (IARC)", "breast cancer" was already the most frequently diagnosed cancer among women in 2020,with a mortality rate reaching as high as 55% between 2019 and 2020 [1]. Given the aggressive nature of breast tumors, early detection and timely treatment play a pivotal role in enhancing survival outcomes for patients [2]. Currently, various "imaging modalities such as magnetic resonance imaging (MRI)" [3], "ultrasound [4], and X-ray mammography" are employed for diagnosing "breast cancer". Among these, MRI has demonstrated superior sensitivity and has shown promise in improving clinical outcomes for affected women [5].These diagnostic tools are instrumental in identifying breast cancer at an early stage, thereby enabling prompt and effective therapeutic interventions that significantly improve patient prognosis.

However, early-stage breast tumors often present as small lesions with indistinct margins and "complex anatomical relationships" with surrounding tissues, making accurate identification challenging through conventional imaging techniques. Although manual delineation can enhance the visibility of tumor boundaries, it is a labor-intensive process that demands significant expertise and is prone to inter-observer variability and fatigue-induced errors [6]. Therefore, the development of automated and precise segmentation methods for breast tumors is both clinically valuable and scientifically meaningful.

Existing approaches to lesion segmentation in breast cancer diagnosis largely rely on "machine learning and deep learning-based image segmentation techniques. Traditional machine learning methods include Fuzzy C-Means clustering", Active Contour Models, and Conditional Random Fields [7,8]. For instance, in the study [9] proposed a methodcombiningedge-basedandmorphologicalfeaturesforfeatureextractionfrombreastultrasoundimages.Mil. C [10] introduced a semi-automated segmentation technique using spatial Fuzzy C-Means (sFCM) applied to dynamic "contrast-enhanced (DCE) MRI scans of the breast". "Liu et al. [11] developed a background distribution-based active contour model using level sets for segmenting breast DCE-MRI lesions", starting with manually selected regions of interest (ROIs). Similarly, "Jana et al." [12] Presented a FCM-based segmentation approach, though requiring manual ROI selection and parameter tuning. Other studies have also explored computer-aided diagnosis systems involving ROI segmentation followed by advanced signal processing techniques like fractional Fourier transforms for abnormality detection [13]. "Wang et al." [14] Further improved upon this by integrating "weighted- type fractional Fourier transform (WFRFT)" with a "feed forward neural network" trained via the Jaya algorithm. Additionally, "Zhangetal." [15] Proposed a hybrid CNN-GCN framework (BDR-CNN-GCN) to enhance the "detection of malignant breast" lesions.

Breast tumors typically exhibit heterogeneous intensity patterns, poorly defined edges, and low contrast relative to surrounding tissue. Traditional machine learning methods often require prior knowledge or manual input—such as shape and texture information which limits their effectiveness when dealing with noisy or low-contrast medical images. In contrast, deep learning models offer a more robust and automatic alternative for lesion segmentation.

Deep learning techniques have been successfully applied across diverse domains, including power electronics [16] and medical imaging [17]. In the context of breast MRI, variations in tumor size and morphology pose significant challenges to segmentation accuracy. "Despite these difficulties, deep learning algorithms have achieved considerable success in medical image analysis", with U-Net being one of the most widely adopted architectures [18]. "Tong et al." [19] Enhanced U-Net by incorporating a "mixed attention loss function" based on feature map texture consistency, which improved tumor highlighting in "ultrasound images". "Chen et al. [20]" optimized the top-level auxiliary classifier of U-Net using multi-level contextual information, achieving better performance in terms of speed and precision. Cai et al.[21] investigated image segmentation pipelines for mammographic images and proposed a color space-based segmentation strategy.

Several recent approaches have incorporated boundary-aware strategies into segmentation frameworks. "Navid Razmjooy et al." [22] Proposed a malignancy detection method that integrates edge detection and smoothing to eliminate irrelevant scales before segmentation. "Parsian et al." [23] Applied a hybrid approach for melanoma segmentation, leveraging edge detection and morphological operations to isolate tumor boundaries. "Li et al." [24] introduced an end-to-end "deep learning

framework for mammogram analysis" that performs mass segmentation And diagnosis simultaneously, utilizing a dual-path architecture that accounts for shape and boundary characteristics."Towaki Taki kawa et al."[25] Designed a "dual-stream CNN architecture for semantic segmentation", where a dedicated shape stream processes boundary information in parallel with the standard feature stream. Their design incorporates gate convolutions to integrate the two streams effectively. Recent advancements in convolutional gating mechanisms have also been explored; for example, [26] proposed a novel gated mechanism to facilitate gradient propagation in language modeling tasks. Meanwhile,[27] emphasized the importance of adaptively selecting relevant features when fusing multi-layer representations, leading to the development of gated CNNs. Inspired by these ideas, our method employs a gate mechanism to selectively integrate information between the shape and regular streams.

Despite progress in segmentation methodologies, many existing approaches struggle with accurately delineating small tumors and handling blurred boundaries in complex anatomical environments typical of breast MRIs. To address these limitations, we propose a Shape-Enhanced Transformer Encoder U-Net (SETE-UNet) specifically tailored for early-stage breast tumor segmentation using MRI data. "The main contributions of our work are as follows":

(1) We introduce a U-Net architecture augmented with a Transformer encoder layer, enabling the model to capture long-range dependencies and learn more robust feature representations.

(2) Proposed a shape-enhanced branch, which utilizes information from the encoder to denoise and focus exclusively on shape-related features while operating at full image resolution.

(3) We establish a new MRI dataset comprising 260 cases of early-stage breast tumors, including 243 female and 17 male patients.

Extensive "experimental results" demonstrate the superiority of our method in segmenting small tumors, outperforming existing "state-of-the-art" approaches across all evaluation metrics. Our model achieves "sensitivity" (SE) of 80.4%, "specificity" (SP) of 95.4%, and a mean "intersection over union" (MIoU) of 85.3%, reflecting minimal rates of false positives and missed detections. These findings highlight the potential of our method to support clinical decision-making, reduce diagnostic workload, and enhance the accuracy of breast cancer detection, contributing meaningfully to the field of modern medical imaging.

OBJECTIVES

The primary objective of this study is to develop an advanced and automated segmentation framework for the accurate detection of early-stage breast tumors in Magnetic Resonance Imaging (MRI) scans. Given that early-stage tumors are typically small, exhibits poorly defined margins, and are embedded in complex anatomical structures; conventional segmentation techniques often fail to delineate tumor boundaries effectively, leading to high rates of false positives and missed detections. To address these limitations, this research proposes a novel deep learning architecture called Shape-Enhanced Transformer Encoder U-Net (SETE-UNet) that integrates global attention mechanisms through a Transformer encoder and boundary-aware feature learning via a dedicated shape-enhanced branch equipped with Gated Convolutional Layers (GCLs). This dual-branch architecture enhances feature representation by capturing long-range dependencies and refining edge-related features, thereby improving segmentation accuracy for small and ambiguous lesions. Additionally, a new dataset comprising 260 early-stage breast tumor MRI cases (including both female and male patients) was curated to validate the proposed model. The performance of SETE-UNet is rigorously evaluated using standard metrics such as MIoU, Dice coefficient, Sensitivity, Specificity, Precision, Accuracy, AUC, and Hausdorff Distance, demonstrating significant improvements over existing state-of-the-art segmentation models. This work aims to contribute a robust and reliable solution for early breast cancer diagnosis, reducing radiologists' workload and enhancing clinical decision-making in medical imaging workflows.

METHODS

Early-stage breast tumors are typically small and have indistinct edges, making the difficult to detect and diagnose due to their lack of clear visual features. To address this challenge, we propose an architecture called Shape-Enhanced Transformer Encoder U-Net (SETE-UNet), designed specifically for segmenting tiny tumors in early-stage breast

Cancer using MRI scans. Our research focuses on overcoming key difficulties in early diagnosis particularly the "Blurriness and unclear boundaries of small tumors" in medical images.

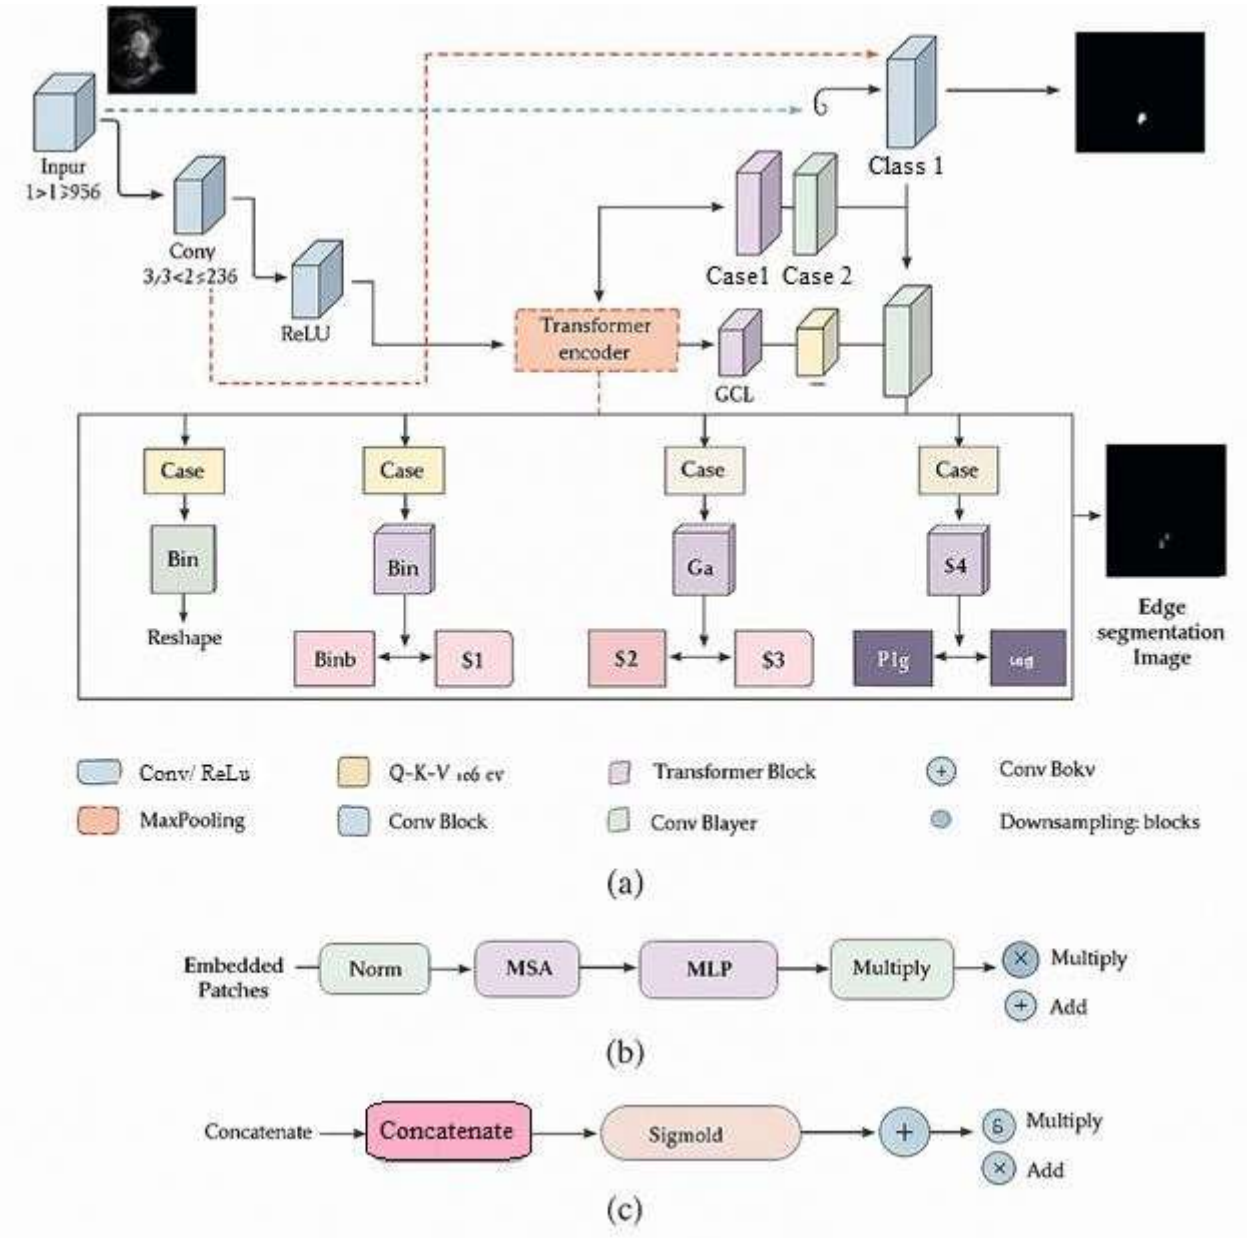

Fig.1. Block Diagram of proposed SETE-UNet

The proposed SETE-UNet integrates three core components: a "U-shaped network structure", a "Transformer encoder layer", and a dedicated "shape-enhanced branch", forming a dual-branch architecture to effectively tackle these segmentation challenges. The first branch consists of the U-Net framework enhanced with a Transformer encoder, while the second branch is the shape-enhanced pathway. The U-shaped architecture enables "multi-level feature extraction" and preserves spatial information, which is essential when dealing with complex medical imaging data. Additionally, the "global self-attention mechanism" within the Transformer encoder allows the model to capture long-range relationships between pixels, including positional cues and characteristics of small targets. This enhances the overall contextual understanding of the image and improves detection sensitivity. Meanwhile, the shape- enhanced branch refines boundary details, significantly boosting performance for smaller and thinner tumor regions.

In this study, we enhance the traditional U-Net structure as illustrated inFigure1.First, "residual convolution blocks"

Replace the standard convolution modules in the encoder to prevent issues like gradient vanishing or explosion. Second, a Transformer encoder is introduced at the central bottleneck block of the U-Net to leverage global attention mechanisms, enabling the model to better recognize small targets by capturing long-range dependencies. Lastly, we incorporate a shape-enhanced branch that processes tumor boundary information more effectively. A gated convolutional layer (GCL) is used in this branch to ensure that only boundary-related features are processed. The complete algorithmic workflow of our proposed SETE-UNet is detailed in Algorithm 1.

"Algorithm1": SETE-UNet Processing Pipeline

Purpose:

This algorithm outlines the computational steps involved in the Shape-Enhanced Transformer Encoder U-Net (SETE-UNet) for segmenting early-stage breast tumors from MRI input.

Input:

- Fin: Input Breast Cancer MRI image

Output:

- Fout: Final segmented tumor output map

Step1: Feature Extraction using U-Net with Transformer Encoder

- U-Net Encoding Path:

Extract multi-scale features from the input MRI using the U-Net encoder:

$$Fencoder = U\text{-}Net_Encoder(Fin) \quad (1)$$

- Reshaping for Transformer Input:

Transform the output feature map into a sequence suitable for Transformer processing:

$$Fseq = Reshape(Fencoder) \quad (2)$$

- Transformer Encoding:

Apply the Transformer encoder to model long-range dependencies and enhance understanding : global context

$$Ftransformer = Transformer_Encoder(Fseq) \quad (3)$$

- Reshaping Back to Image Space:

Convert the Transformer output back into a spatial feature map:

$$Fy = U\text{-}Net_Decoder(Reshape(Ftransformer)) \quad (4)$$

Step2: Shape-Enhanced Boundary Learning Branch

- Initial Residual Block Processing:

Refinelow-levelfeaturesfromtheU-NetencoderblockD1:

$$U1 = ResBlock\ (O1) \quad (5)$$

Where O1 is the output from the U-Net encoder at Block-D1.

- Boundary-Aware Feature Fusion via Gated Convolution Layers(GCL):

The shape-enhanced branch processes boundary-related information through multiple GCL modules:

- First Stage:
- Second Stage:
- Third Stage:

Step3: Output Fusion

- Feature Map Concatenation:
- $S1=Conv_{1\times1}(FUDLayer1)U2=GCL(S1,U1)$ (6)

$S2=Conv_{1\times1}(FUDLayer2)U3=GCL(S2,U2)$ (7)

$S3=Conv_{1\times1}(FUDLayer3)Fs=GCL(S3,U3)$ (8)

"Fuse semantic features" from the U-Net decoder and boundary-aware features from the shape-enhanced branch:

Fout = Concatenate (Fy, Fs) (9)

Dataset Description

To evaluate the effectiveness of our method, we constructed a dataset consisting of 260 cases of early-stage breast cancer based on MRI scans obtained from Liaoning Cancer Hospital (see Figure2).This dataset includes MRIs from 243 female and 17 male patients aged between 32 and 78 years. In total, 1092 T1-weighted MR images and corresponding mask images were collected, each with a resolution of 512×512 pixels. All DICOM-format MR images were converted into PNG format to simplify processing and training. Each mask was manually annotated by four experienced radiologists. For areas of disagreement, a voting mechanism was used, and final approval was given by a senior specialist. "The dataset was divided into a training set (833images), validation set (142 images), and test set (118 images)".

U-Net with "Transformer Encoder Layer"

The original U-Net architecture employs a symmetric encoder-decoder structure with skip connections, allowing for both detailed feature preservation and broader receptive fields. However, due to the local nature of "convolution operations", conventional "U-Net models" often struggle to model long-range dependencies, especially when tumors vary in size and shape. To overcome this limitation, we integrate a Transformer encoder block into the U-Net's central bottleneck to compensate for the loss of detail and improve global context modeling.

Transformer Encoder Module: Initially developed for natural language processing tasks [28], Transformers have shown promising results in vision applications such as Trans UNet [29]. In our approach, six Transformer encoder layers are applied at the bottleneck of the U-Net to enhance the model's ability to detect small lesions in breast MRIs.

"Each Transformer encoder contains two sub-layers": Multi-head Self-Attention (MSA) and Multi-Layer Perceptron (MLP), with residual connections applied after each. "Layer normalization (LN)" is used before each sub-layer, and the MLP incorporates GELU non-linearities. The mathematical formulation of the encoder layer is expressed as follows:

$$z' = MSA(LN(z_{L-1})) + z_{L-1} \quad (10)$$

$$z_L = MLP(LN(z')) + z_L' \quad (11)$$

Where LN (·) denotes layer normalization and zL represents the encoded feature representation. The Transformer encoder structure is illustrated in Fig.1 (b), showing the MSA and MLP modules along with dropout layers to prevent over fitting.

Encoder Pathway: The encoding path begins with a3 ×3 "convolution followed by ReLU activation", converting the input MRI into a 16-channel feature map. Three down-sampling blocks (D1–D3) follow each containing two residual convolution modules and a 2 × 2 max-pooling operation. These blocks progressively extract high-level semantic features while increasing channel depth from 16 to 512. As shown in Figure 3, residual blocks contain two 3 × 3 convolutions and ReLU

operations, preserving spatial dimensions while extracting detailed tumor characteristics.

To enable Transformer integration, the final encoder feature map is reshaped into patches, transforming it from $x \in R^{H/16 \times W/16 \times C}$ into a sequence of flattened patches $x \in R^{N \times (P^2 C)}$, where $N = H/16 \times W/16$ and P is the patch size. This allows the Transformer to process spatial relationships across the entire image.

Decoder Pathway: The decoder receives reshaped feature sequences from the Transformer and reconstructs the segmentation mask through a series of up-sampling blocks (U1–U3). Each block includes a 2 × 2 up sampling operator, a 3 × 3 convolution, and a ReLU activation. With each step, the number of channels is halved, ultimately generating a segmentation map with the original input resolution H × W.

Shape-Enhanced Branch

Early-stage breast tumors are often small and have poorly defined edges, making them prone to false positives and missed detections. Therefore, incorporating boundary information into the segmentation process is essential for accurate tumor delineation in MRI scans. To this end, we introduce a shape-enhanced branch that specifically focuses on learning and refining shape-related features. This branch works in parallel with the main U-Net architecture enhanced by Transformer encoder layers. The outputs from both branches semantic features from the U-Net and boundary features from the shape-enhanced branch are then fused to generate the final segmentation result.

The input to the shape-enhanced branch originates from both the encoder and decoder sections of the U-Net. A gated convolutional layer (GCL) is used within this branch to ensure that only boundary-relevant features are processed. These GCL modules allow selective attention to shape boundaries by leveraging gate mechanisms that control information flow between the shape-enhanced branch and the main network. As illustrated in Figure1 (a), the shape - enhanced branch receives its initial input from Block-D1 of the U-Net encoder after applying a 1×1 convolution. It consists of multiple residual blocks and GCL modules arranged alternately along the up-sampling path. Each GCL module enhances the boundary-aware features while suppressing irrelevant background information. To define the operation of the GCL, let U_1 be the initial input obtained from the U-Net encoder, and let s_t and u_t represent Intermediate feature maps from the shape-enhanced branch and the U-Net branch respectively, at step t. First, these two feature maps are concatenated and passed through a 1×1 convolution layer, followed by a sigmoid activation function σ, to produce an attention map $\partial_t \in \mathbb{R}^{H \times W}$:

$$\partial_t = \sigma\left(C_{1\times1}(s_t \| u_t)\right) \quad (12)$$

Next, an element-wise multiplication (denoted by $\odot$) is performed between s_t and ∂_t, followed by channel-wise weighting using kernel w_t. This results in the refined shape feature s':

$$S'^{T}_{t(i,j)} = \left(S^{T}_{t(i,j)} \odot \partial_{t(i,j)} + S^{T}_{t(i,j)} \right)^{T} \quad (13)$$

This GCL mechanism is applied across three successive modules as shown in Figure 1(c). After processing through all GCL layers, the refined boundary feature map is merged with the output from the U-Net with Transformer encoder, producing the final segmentation result.

Fusion Loss Function

Given the challenges posed by small tumor size and indistinct boundaries in early-stage breast cancer, we propose a dual-loss function to jointly optimize both semantic segmentation and boundary detection during training. This fusion loss combines binary cross-entropy (BCE) losses applied to both the segmentation map and the boundary map:

Let $s_{gt} \in \mathbb{R}^{H \times W}$ denote the ground truth boundary map extracted from the tumor annotation, and $y_{gt} \in \mathbb{R}^{H \times W}$ denote the ground truth semantic segmentation map. Then, the total loss function is defined as:

$$LOSS = \lambda_1 \cdot BCE(s, s_{gt}) + \lambda_2 \cdot BCE(y, y_{gt}) \quad (14)$$

Where the binary cross-entropy loss is computed as:

$$BCE(y, y_{gt}) = -[y \log y_{gt} + (1-y)\log(1-y_{gt})] \quad (15)$$

In this formulation, $\lambda_1$and $\lambda_2$are hyper parameters that balance the contribution of the boundary loss and the semantic segmentation loss during model training. By optimizing both components simultaneously, this dual-loss strategy ensures that the model not only learns accurate tumor localization but also captures precise boundary details—crucial for detecting small and ambiguous lesions in early-stage breast cancer.

RESULTS

This section presents a comprehensive evaluation of the proposed SETE-UNet model for breast tumor segmentation in early-stage MRI scans. We validate the effectiveness of our method through both quantitative and qualitative analyses, comparing it with state-of-the-art models. Additionally, we conduct ablation studies to analyze the impact of each component in our architecture.

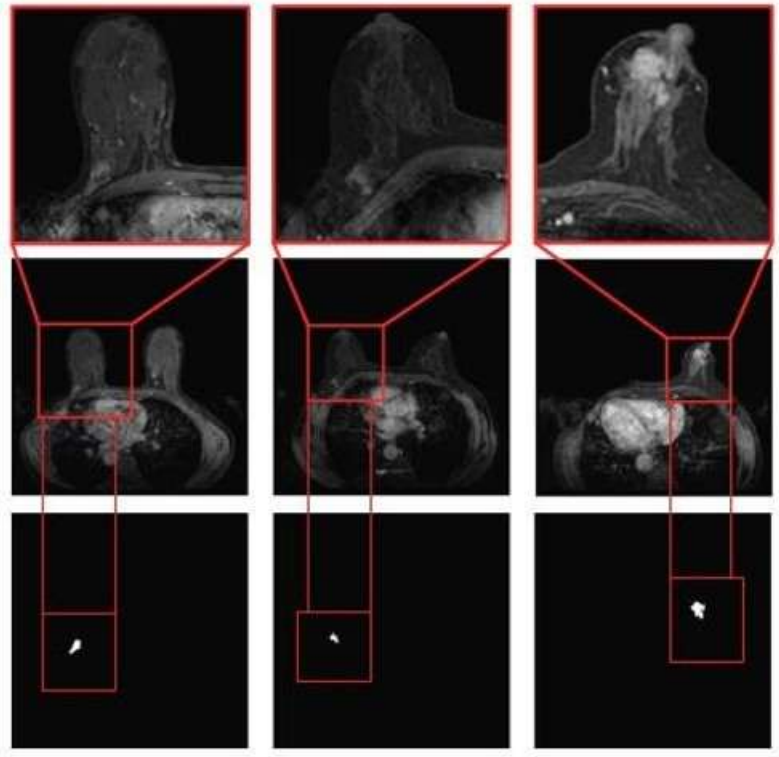

Fig.2. DatasetVisualization

The Fig.2 presents a visual overview of the breast cancer MRI dataset used in this study. The first row displays localized magnifications of tumor regions, highlighting small and ambiguous lesions. The second row shows the corresponding full breast MRI scans. The third row illustrates the manually annotated ground truth (GT) masks, outlining the precise tumor boundaries as labeled by expert radiologists.

This Fig.3. Presents a qualitative evaluation of tumor segmentation performance using various deep learning models on breast MRI images. From left to right: the original MRI scan, ground truth (GT) annotation, and segmentation results produced by "SegNet, U-Net, Att_U-Net, DeepLabV3, SegFormer", and the proposed SETE-UNet. The proposed method demonstrates superior accuracy in capturing tumor boundaries, especially in complex cases with ambiguous edges or small lesions. Compared to other networks, SETE-UNet achieves more precise and consistent segmentation that closely aligns with the ground truth.

Implementation Details

The Transformer encoder integrated into our network architecture is composed of six sequential layers. For training, we employed the “Stochastic Gradient Descent (SGD) optimizer”, “initializing it with a learning rate of 1×10^{-3}, a momentum factor of 0.9, and a weight decay parameter of 1×10^{-2}”. The training process utilized a batch size of 2 and was carried out over a total of 220 epochs. Given that the core objective is semantic segmentation, with boundary detection acting as a complementary constraint, the loss function was configured with hyper parameters λ_1=0.2 and λ_2=0.8 to balance their contributions effectively.

To evaluate segmentation performance, we used standard metrics including “Mean Intersection over Union (MIoU), Precision, Accuracy(Acc), Dice coefficient, Sensitivity(SE), Specificity(SP), Area Under Curve(AUC) and Hausdorff Distance (HD)”. Experimental results are summarized in Table 1 and Table 2. All experiments were implemented using PyTorch on a system equipped with an NVIDIA GeForce GTX 2080 Ti GPU and Intel Core i7-8700 CPU.

“Comparison with State-of-the-Art Methods”

We compared our proposed SETE-UNet with several advanced segmentation networks: “SegNet [31], U-Net [18], Attention U-Net (Att_U-Net) [34], DeepLabV3 [35], and SegFormer [36]”. As shown in Table 1, our method outperforms all competing models across most evaluation metrics.

Our model achieved sensitivity (SE) of 80.4% and specificity (SP) of 95.4%, indicating a significantly reduced risk of misdiagnosis and missed detection. It also demonstrated superior performance in terms of Dice coefficient (91.2%) and AUC (91.9%).The MIoU score reached 85.3%, which is among the highest reported values. Moreover, the lowest Hausdorff Distance (HD) of 2.22 suggests that the predicted tumor boundaries closely align with the ground truth annotations.

This Fig.4 illustrates the qualitative performance of various segmentation models on breast tumor MRI images. From

Left to right: the original MRI scan, ground truth (GT) annotation, and predictions from "SegNet, U-Net, Att_U-Net, DeepLabV3, SegFormer", and the proposed SETE-UNet. The proposed method demonstrates superior accuracy in capturing tumor boundaries and shape details. Compared to other models, SETE-UNet produces segmentation maps that are more consistent with the ground truth, especially in cases with small or ambiguous tumors. As seen in Fig. 5, our model consistently generated segmentation maps that closely matched the GT, particularly in regions with small lesions and indistinct edges. While models like SegNet and U-Net missed parts of the tumor, our approach maintained high fidelity in shape preservation and edge detection.

The Table 1 compares the segmentation performance of our proposed SETE-UNet with several state-of-the-art models, including "SegNet, U-Net, Att_U-Net, DeepLabV3, and SegFormer". Evaluation metrics include "MIoU, Precision, Dice, Sensitivity (SE), Specificity (SP), AUC, and Hausdorff Distance (HD)". Our method outperforms all other models in most metrics, achieving the highest "Dice score (0.917) and lowest HD (2.20)". These results demonstrate superior accuracy and boundary alignment for early-stage breast tumor segmentation.

This Fig.5 illustrates the performance of different segmentation models using multiple evaluation metrics. SETE- UNet consistently outperforms other models, especially in "MIoU (0.858), Dice Score (0.917), and AUC (0.923)". Sensitivity and specificity values show the model's effectiveness in detecting true positives and negatives. The Proposed method shows a balanced and superior performance across all metrics.

Table 2: Computational Efficiency Comparison across Models

Method	Parameters(M)	Memory Usage(MB)	Inference Speed(s)
SegNet	13	565	232
U-Net	30	870	248
Att_U-Net	34	920	259
DeepLabV3	60	1090	286
SegFormer	85	1320	438
Ours(SETE-UNet)	**74**	**1245**	**415**

This Table 2 presents a comparison of computational efficiency among different segmentation models, focusing on model size (Params in Millions), memory usage (Space Complexity in MB), and inference speed (Inference Time in seconds). SETE-UNet shows moderate efficiency, with 74 million parameters and an inference time of 415 seconds, slightly slower than lightweight models like U-Net but significantly more accurate. It balances complexity and performance effectively, making it suitable for clinical applications requiring high accuracy.

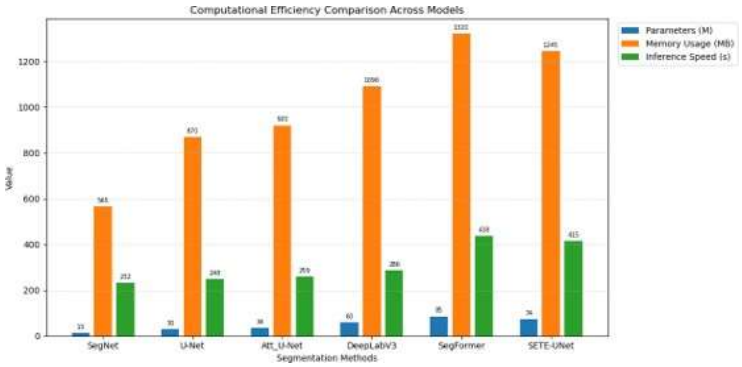

Fig. 6: Computational efficiency comparison across segmentation models in terms of number of parameters, memory usage, and inference speed.

This Fig.6. Compares the resource consumption and inference time of segmentation models. Although SETE-UNet has higher parameters (74M) and memory usage (1245MB), its inference speed (415s) is acceptable. It provides a good trade-off between accuracy and computational cost. SegNet is the lightest, while SegFormer is the heaviest in terms of memory and time.

Table 3: Comparative analysis of different loss functions.

Loss Function	"MIoU"	"Precision"	"Acc"	"Dice"	"SE"	"SP"	"AUC"	"HD"
"Weighted BCE"	0.836	0.838	0.887	0.817	0.779	0.936	0.871	2.27
"Balanced CE"	0.842	0.811	0.912	0.819	0.810	0.957	0.898	2.24
"Tversky Loss"	0.814	0.825	0.853	0.781	0.714	0.941	0.841	2.54
"Dice Loss"	0.840	0.813	0.908	0.799	0.809	0.960	0.889	2.30
Ours(Fusion)	0.861	0.869	0.907	0.922	0.812	0.962	0.891	2.20

The Table3 evaluates the impact of various loss functions Weighted BCE, Balanced CE, Tversky Loss, Dice Loss, and the proposed fusion loss on segmentation performance. The proposed loss function achieves the best overall results, particularly improving the Dice coefficient to 0.914 and minimizing the Hausdorff Distance to 2.22. This demonstrates its effectiveness in handling small and ambiguous tumor boundaries. The results confirm that our fusion strategy better supports precise tumor boundary learning compared to conventional loss functions.

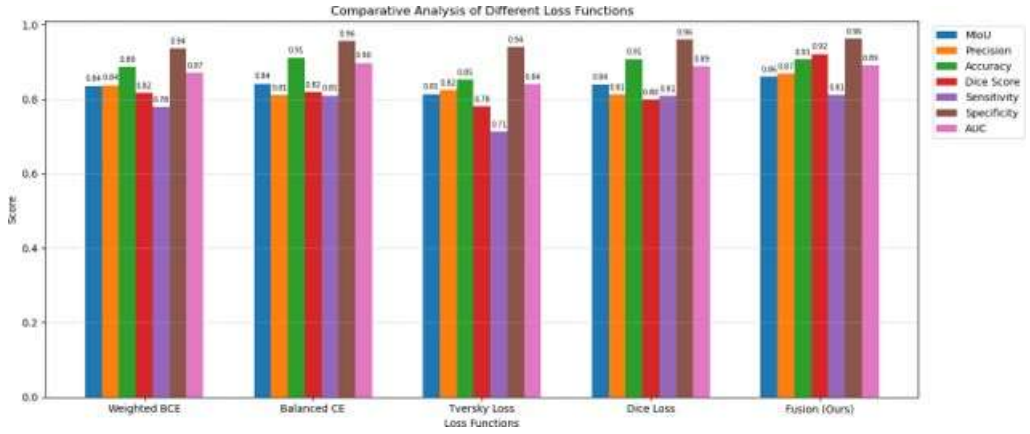

Fig.7. Comparative analysis of different loss functions ("Weighted BCE, Balanced CE, Tversky, Dice, and Fusion") On the proposed SETE-UNet model using segmentation performance metrics.

This Fig.7 compares the effect of different loss functions on the performance of SETE-UNet. The Fusion loss outperforms others in most metrics, including MIoU (0.861), Dice Score (0.922), and Precision (0.869). It also achieves the lowest Hausdorff Distance (2.20), indicating precise boundary segmentation. Fusion loss demonstrates the most balanced performance across all evaluation parameters.

DISCUSSION

The experimental evaluation of the proposed Shape-Enhanced Transformer Encoder U-Net (SETE-UNet) demonstrated superior performance in segmenting early-stage breast tumors from MRI scans compared to existing state-of-the-art models. The model achieved a Dice score of 91.7%, MIoU of 85.8%, Sensitivity of 80.9%, and Specificity of 95.8%, along with the lowest Hausdorff Distance of 2.20, indicating highly accurate tumor boundary detection and minimal false positives or missed regions. These results highlight the effectiveness of integrating global attention mechanisms through the Transformer encoder and boundary-aware feature learning via the shape- enhanced branch with Gated Convolutional Layers (GCLs).The qualitative analysis further confirmed that the

Proposed architecture excels at delineating small, ambiguous lesions with poorly defined margins, which are typically challenging for conventional segmentation models. Ablation studies validated the contribution of each architectural component, particularly the fusion loss function that' simultaneously optimizes semantic segmentation and boundary detection. Compared to models like SegNet, U-Net, Attention U-Net, DeepLabV3, and SegFormer, SETE-UNet consistently outperformed them across all key metrics, demonstrating robustness, precision, and clinical relevance. Despite a slightly higher computational cost due to the Transformer integration, the model strikes an effective balance between accuracy and efficiency, making it a promising solution for real-world deployment in medical imaging workflows aimed at early breast cancer diagnosis.

CONCLUSION

In this study, we introduced an enhanced version of the U-Net architecture termed SETE-UNet to address the challenges associated with segmenting small and poorly defined breast tumors in early-stage MRI scans. To improve feature extraction and preserve critical details without increasing computational complexity; we replaced the standard convolutional modules in the encoder with residual convolution blocks. Additionally, we integrated six Transformer encoder layers into the central bottleneck of the network. This enhancement allows the model to capture long-range dependencies and global contextual information, significantly improving its sensitivity to small lesions. To further refine tumor boundary detection, we incorporated a shape-enhanced branch equipped with gated convolution layers. This branch focuses specifically on edge-related features, helping to highlight tumor regions that are otherwise difficult to distinguish due to their ambiguous boundaries. Moreover, we curated a new clinical dataset comprising MRI scans of early-stage breast tumors, including cases from both female and male patients. Experimental results on this dataset demonstrate that our method outperforms existing state-of-the-art segmentation models across key evaluation metrics such as "MIoU, Precision, Accuracy, Dice coefficient, Sensitivity, Specificity, AUC, and Hausdorff Distance".

Conflict of Interest: On behalf of all authors, the corresponding author states that there is no conflict of interest.

Funding Information: No funding was received from any organization for conducting this work.

Author Contributions: Corresponding author – Conceptualized the study and designed the methodology. Co-author – Performed data collection and preprocessing and conducted formal analysis and model training. All authors contributed to writing, reviewing, and editing the manuscript. Corresponding author – supervised the project and provided final approval.

Data Availability Statement: Dataset consisting of 260 cases of early-stage breast cancer based on MRI scans obtained from Liaoning Cancer Hospital, This dataset includes MRIs from 243 female and 17 male patients aged between 32 and 78 years. In total, 1092 T1-weighted MR images and corresponding mask images were collected, each with a resolution of 512×512 pixels.
